the main channel through which it is metabolized is via the liver, where it is converted to its active form, desmethylcitalopram, which is then excreted in the urine. The half-life of citalopram is approximately 35 hours, and it is considered to be a long-acting antidepressant. It is also available in a transdermal patch form, which is used for the treatment of depression in patients who are unable to take oral medication. The patch is applied to the skin and provides a steady release of the drug over a period of 24 hours. It is important to note that citalopram should be used with caution in patients who are taking other medications, particularly those that affect the liver or the kidneys. It is also important to avoid alcohol and grapefruit juice while taking citalopram, as they can interfere with its effectiveness. If you are taking citalopram, it is important to follow your doctor's instructions carefully and to report any side effects immediately.
